# What is Let's Encrypt?

Let's Encrypt is a **Certification Authority (CA)** that issue **free** SSL/TLS certificates

- ▶ From 5 December 2015 L.E. is available in **Public Beta**
- ▶ L.E. has released more than **480 k** certificates
- ▶ It's major focus is **automation** of processes.
- ▶ **<https://letsencrypt.org/>**

**Let's Encrypt! Free

2012 Project begins inside **Mozilla**

11-2014 Let's Encrypt **publicly announced**

01-2015 The **ACME** protocol submitted to **IETF** for  
standardization

04-2015 **ISRG** (Internet Security Research Group) and  
**Linux Foundation** join the project

09-2015 Issued the first certificate for  
**helloworld.letsencrypt.org**

10-2015 L.E. intermediate certificate becomes **cross-signed**  
by IdenTrust. (*Let's Encrypt is trusted!*)

12-2015 **Public beta!**

## Architecture

The Let's Encrypt system is based on **3 components**: a **server**, a **client** and the **protocol** that defines the communication rules between server and client

The server is called **Boulder** and it's completely written in **Go**. It's responsible of handling all the procedures for **issuing**, **renewal** and **revocation** of certificates.

It's basically an HTTPS server that exposes a **RESTful** interface.

The client is called (obviously) **letsencrypt** and it's completely written in **Python**. It's responsible for interaction with the remote server and it **handles your certificates**.

- ▶ Download through .deb package **letsencrypt** (only on debian *sid/stretch*).
- ▶ Clone the **git repository**.

# Plugins

The client's main purpose is to **simplify and automate** the whole process of authentication and creation of the certificate.

For this reason the client comes with several plugins, useful to automatically setup the new certificates on popular web servers: **apache** and **nginx**.

The protocol used by Let's Encrypt is called **Automated Certificate Management Environment (ACME)**.

ACME is based on exchanges of signed **JSON** files (a.k.a. **JWS, Json Web Signature**). These documents contain all the requests and the responses between the client and the server.

These documents **must** be exchanged over **HTTPS**.

## Automatic Certificate Management Environment (ACME)

draft-barnes-acme-04

### Abstract

Certificates in the Web's X.509 PKI (PKIX) are used for a number of purposes, the most significant of which is the authentication of domain names. Thus, certificate authorities in the Web PKI are trusted to verify that an applicant for a certificate legitimately represents the domain name(s) in the certificate. Today, this verification is done through a collection of ad hoc mechanisms. This document describes a protocol that a certificate authority (CA) and an applicant can use to automate the process of verification and certificate issuance. The protocol also provides facilities for other certificate management functions, such as certificate revocation.

 <https://github.com/letsencrypt/acme-spec>

The ACME protocol is aimed to:

1. **Prove** that we are the owners of a specific domain, say *example.com*
2. **Obtain** a new certificate for the domain *example.com*
3. **Revoke** or **Renew** a certificate for the domain *example.com*

# Security

Let's Encrypt! Free  
certificates for  
everyone!

Nicola Corti

All the interactions between client and servers are encrypted with a **public/private key pair** generated during the first execution of the client.

In order to **prove** that we are the owners of the domain, the server sends us a set of **challenges** that we must solve.

Every interaction with the server is marked with a **nonce** number that allows to avoid **Replay** attacks.

# Challenges

Let's Encrypt! Free  
certificates for  
everyone!

Nicola Corti

The server can decide to send one or more challenge from the followings:

Type	Description
<b>Simple HTTP</b>	You must place a <b>token file</b> inside your web-server root folder. Both HTTP and HTTPS are accepted
<b>DNS</b>	You must provide a token inside a <b>TXT record</b> of your DNS server
<b>Proof of possession</b>	You must <b>sign a document</b> using a keypair that the server already consider yours
<b>Domain Validation with Server Name Indication</b>	You must configure a <b>TLS server</b> on a specific IP address (through an A record inside the DNS).

# DV Certificates

Let's Encrypt! Free  
certificates for  
everyone!

Nicola Corti

## DV

All the certificates issued from L.E. are **Domain Validated** certificates. They basically prove that you are the owner of a specific domain, nothing more.

**Organization Validation** and **Extended Validation** certificates require to explicitly verify the identity of the subject that is requesting a certificate.

# Validity

All the certificates have a **90 days** validity. After the expiry, the certificates are not valid anymore and the browsers will raise security errors.

## *90-days validity*

This is nothing new on the web. Having certificates with a reduced validity could help to limit damage from key compromise and mis-issuance.

You will receive *remind emails* whenever a certificate is near to expire. Certificate renewal can be automated with a **cron** task.

# Requirements

The client minimal requirements are:

- ▶ **Unix like** system.
- ▶ **Python 2.6** or **2.7**.
- ▶ **root** rights on the system.

The **apache** setup plugins works only on Debian based system:  
**Ubuntu 12.04+** and **Debian 7+**

# Download

Let's Encrypt! Free  
certificates for  
everyone!

Nicola Corti

First, let's download the **letsencrypt** client.

On Debian *sid/stretch*:

```
$ sudo apt-get install letsencrypt  
$ letsencrypt --help
```

On other OS:

```
$ git clone https://github.com/letsencrypt/letsencrypt  
$ cd letsencrypt  
$ ./letsencrypt-auto --help
```

From now on we will use **letsencrypt-auto** for all the commands, assuming to proceed with clone of the repository.

If you want to automatically configure **Apache** with the generated certificates you can invoke:

```
$ ./letsencrypt-auto --apache -d example.com -d www.example.com
```

With **--apache** we are enabling the apache plugin, and with **-d** we are giving the list of involved domains.

You can use the plugins with **authentication** support (A column) just to obtain the certificates **without installation**.

Simply add the option **certonly** to the command line.

### Standalone example

```
$ ./letsencrypt-auto --standalone-supported-challenges \  
http-01 certonly -d example.com
```

This command will start a standalone webserver on port 80 and it will obtain the certificate for example.com

[Intro](#)[Sponsors](#)[History](#)[Why?](#)[Server](#)[Client](#)[Protocol](#)[Security](#)[Challenges](#)[The protocol](#)[Cert revocation](#)[Certs](#)[DV](#)[Cross Signing](#)[Setup](#)[Requirements](#)[Download](#)[Run](#)[Plugins](#)[Revoke](#)[Renewal](#)[Update](#)[Screens](#)[Conclusions](#)[Drawbacks](#)[Resources](#)

All the certificates and the auth keys will be saved into  
**/etc/letsencrypt**.

Inside this folder you will find all the **certificates** and all the **public/private keys**. It's **extremely** recommended to make a **backup** of this folder to a secure place.

Inside **/etc/letsencrypt/live/example.com/** you will find symlinks that will be updated after every renewal.

# Renewal

The renewal process it's extremely easy, you can simply invoke **letsencrypt** without parameters.

You can also use the **--renew-by-default** to perform the automatic renewal of the certificate without user interaction.

In this way, it's possible to schedule a **cron** task to automatically renew the certificates before the expiry.

Let's Encrypt! Free

# Update

Since Let's Encrypt it's a public beta, it's fundamental to keep the client up to date.

On Debian *sid/stretch*:

```
$ apt-get update && apt-get upgrade
```

On other OS:

```
$ cd letsencrypt  
$ git pull
```

# General usage

During everyday usage, you can simply invoke letsencrypt without parameters. The *terminal UI* will guide you through the desired process.

You simply have to answer to the client questions.

Having only **too much parameters** could be hard to remember. The UI will help on this, but the parameter still give the flexibility to embed the client inside **scripts**.

# Drawbacks

- ▶ No support for **Organization Validation** or **Extended Validation**, too hard to automate.
- ▶ No support for **wildcards** (\*.example.com), maybe in the future.
- ▶ Only HTTP challenge is supported (public beta), DNS challenge support is not already available.
